

Binding and dimensionality:

Consider a spherically symm pot. $U(r) = -U_0 \Theta(a-r)$.

Are there bound states?

Clearly yes if U_0 is large!

Consider a trial state localized with ξ inside potential well. If $k \cdot E$ of state $> U_0$ state delocalizes. What happens when $U_0 < \frac{\hbar^2}{2m\xi^2}$?

$$\xi = \lambda a$$

Variational energy \rightarrow

$$E \approx \frac{\hbar^2}{2m\xi^2} - U_0 \left(\frac{a}{\xi}\right)^d$$

$$= \frac{\hbar^2}{2ma^2} \lambda^{-2} - U_0 \lambda^{-d}$$

diff. w.r.t. λ

$$-2T_0 \lambda^{-3} + d U_0 \lambda^{-(d+1)} = 0$$

$$\Rightarrow \lambda = \left(\frac{2T_0}{dU_0}\right)^{\frac{1}{2-d}}$$

$$\therefore E = -\left(\frac{2}{d}\right)^{\frac{2}{d-2}} \left(1 - \frac{2}{d}\right) T_0^{\frac{d}{d-2}} U_0^{-2/(d-2)}$$

$d=1$,

$$E < 0 \\ = -\frac{U_0^2}{4T_0}$$

$$\lambda = \frac{2T_0}{dU_0}$$

$d=2$, ~~$\lambda \rightarrow \infty$~~ $E \approx 0$. (localized states with ballistic dip.)

$d > 2$

$E > 0$

no.

bound states

ballistic dip.

Instability of Fermi surface to attraction

What is a Fermi surface?

Simple model of 2 e^- . $\vec{r}_1 + \vec{r}_2$ (other e^- are like free particles)

Assume the 2 chosen e^- do not χ^+ with others
Other e^- forbid them from occupying levels with $k < k_F$.

Behaviour of relative coord: $(\vec{r}_1 - \vec{r}_2)$

$$\psi(\vec{r}_1, \vec{r}_2) = \psi(\vec{r}_1 - \vec{r}_2) = \sum_k g(\vec{k}) e^{i\vec{k} \cdot (\vec{r}_1 - \vec{r}_2)} \quad \text{--- (1)}$$

rel. prob coeff of a plane wave state.

where one e^- is in $\hbar\vec{k}$ + the other has momentum $-\hbar\vec{k}$

Effect of the other $N-2$ particles

Since all $k < k_F$ states are occupied,

$$g(\vec{k}) = 0 \text{ for } |\vec{k}| < k_F$$

Schrodinger eqn.

$$-\frac{\hbar^2}{2m} [\Delta_1 + \Delta_2] \psi + V(\vec{r}_1, \vec{r}_2) \psi = (E + 2E_F) \psi \quad \text{--- (2)}$$

E is measured from the Fermi energy. $2E_F = \frac{\hbar^2 k_F^2}{m}$

χ^+ . $V(\vec{r}_1, \vec{r}_2) = V(\vec{r}_1 - \vec{r}_2) = \sum_k V_k e^{i\vec{k} \cdot (\vec{r}_1 - \vec{r}_2)} \quad \text{--- (3)}$
Using (1) & (3) in (2), we obtain for each plane wave component

$$\frac{\hbar^2 k^2}{m} g(\vec{k}) + \sum_{\vec{k}'} V_{\vec{k}-\vec{k}'} g(\vec{k}') = (2E_F + E) g(\vec{k})$$

* spin singlet state & centre of mass at rest.

$$g(\vec{k}) = g(-\vec{k}) \quad \sum_{\vec{k}} |g(\vec{k})|^2 = 1$$

To get an analytical soln. we assume a very small ω_D

$$V_{\vec{k}, \vec{k}'} = -V \quad \text{if } E_f < \frac{\hbar^2 k^2}{2m} < E_f + \hbar\omega_D$$

$$+ E_f < \frac{\hbar^2 k'^2}{2m} < E_f + \hbar\omega_D$$

$$= 0 \quad \text{otherwise} \quad \omega_D \rightarrow \text{Debye freq.}$$

$$-V \sum_{\vec{k} \neq \vec{k}'} g(\vec{k}') = C$$

$$\Rightarrow g(E) = \frac{C}{E + 2E_f - \frac{\hbar^2 k^2}{2m}}$$

Self consistency demands that

$$-VC \sum \frac{1}{E + 2E_f - \frac{\hbar^2 k^2}{2m}} = C$$

$$V = V \sum_{\vec{k}} \frac{1}{\frac{\hbar^2 k^2}{2m} - E - 2E_f}$$

sum is effected over the annulus of width ω_D $E = \frac{\hbar^2 k^2}{2m}$

Using $\xi = \frac{\hbar^2 k^2}{2m} - E_f \rightarrow$ single particles energy $k \cdot d^{-1} dk \cdot E$

density of states $N(\xi) = 2 \left[\frac{4\pi k^2}{(2\pi)^3} \frac{dk}{d\xi} \right]_{\xi}^{E_f + \hbar\omega_D}$

we have $\frac{1}{V} = \int_0^{\hbar\omega_D} \frac{1}{2\xi - E} N(\xi) d\xi \rightarrow \frac{E}{TE}$

Assuming $\omega_D \ll E_F$, $N(E) = \text{cte} \equiv$ fermi energy value!
 $N(0) =$

$$1 = \frac{N(0)V}{2} \ln \frac{E - 2\hbar\omega_D}{E}$$

$$\left| \frac{1}{2} \ln \left| \xi - \frac{E}{2} \right| \right|_0^{\hbar\omega_D}$$

$$\frac{1}{2} \ln \frac{\hbar\omega_D + E/2}{E/2}$$

If the interaction is very weak
 $N(0)V \ll 1$ then)

$$E = -2\hbar\omega_D \exp - \frac{2}{N(0)V}$$

\implies weak bound state of $2 e^{-s}$ for arbitrarily weak attract. X^2 !
 Crut always true in 3D... 2 He molecule is unbound inspite of $-\frac{1}{r^6}$ vd Waals X^6 !

air state is in a zero momentum state.
 If we take into account the spin, the solns. to the eqns. are angular momentum eigenstates, so $g(k)$ should have definite parity. $g(k) = g(-k)$ or $g(k) = -g(-k)$.
 we consider $g(k) = g(-k)$ & this corresponds to symm. spatial fn. & hence a spin singlet state to restore antisymm nature of fermion wavefn.
 \rightarrow Pair state having finite $q \rightarrow$ bound state only for exponentially small q .
 $E \rightarrow E + \mathcal{O}(q^{1/2})$

What does the wave fn. look like?

(s-wave orbital state)

$$\psi(r) = \frac{1}{r} \frac{d}{dr} \int_0^{R_0} \frac{\cos k_r r}{2\epsilon_k + |E|}$$

$$\epsilon_k = \frac{\hbar^2 (k^2 - k_f^2)}{2m}$$

$$= \frac{\hbar^2 k^2}{2m} = E_f$$

$R_0 \rightarrow$ cut off wave vector k
 $r = |\vec{r}_1 - \vec{r}_2|$

General structure of $\psi \rightarrow \sum$ terms of $(\cos k_f r, \sin k_f r) \times$
 decreasing fn. of r

$\frac{1}{r}$ for small r . $\frac{1}{r^2}$ for larger r .

Cross over happens at $r \sim \frac{\hbar v_F}{|E|} \sim \frac{\hbar v_F}{\hbar \omega_D} \exp \frac{2}{N(0)V} \equiv \xi$
 $v_f = \frac{\hbar k_f}{m}$

The bound state has a radius ξ_c in the sense
 prob of finding particles at $r \gg \xi \rightarrow 0$ as $\frac{1}{r}$

But for small r $\psi(r) \sim \frac{\sin k_f r}{R_f r}$

Generalize to finite T

assume that pair can only occupy states $k \uparrow, -k \downarrow$

if $N-2$ e^- do not occupy them.

At finite T , probability for occupation of this pair is

$$\frac{1}{(1 + e^{\beta \epsilon_k})^2}$$

Replains $p(\epsilon) = N(0) \Theta(\epsilon) \rightarrow \frac{N(0)}{(1 + e^{\beta \epsilon})^2}$

$$\frac{1}{V} = N(0) \int_{-\infty}^{\infty} \frac{dE}{(E-E_0)(1+e^{\beta E})^2}$$

But E can have any sign of finite T .

~~(A)~~

Singularity at $E=0$ is removed!

equivalent to replacing lower limit by $k_B T$ (not 0!)

(A) has no $E < 0$ soln. if condition not satisfied

$$\int_{k_B T}^{k_{WD}} \frac{dE}{2E} > \frac{1}{N(0)V}$$

$$\ln \frac{k_{WD}}{k_B T} = \frac{2}{N(0)V}$$

$$\frac{k_B T}{k_{WD}} = e^{-\frac{2}{N(0)V}}$$

i.e. above a critical T_c

$$T_c \sim \frac{k_{WD}}{k_B} \exp\left(-\frac{2}{N(0)V}\right)$$

(order of mag estimates)

3 features

- exponentially small energy of bound state
- " large radius of pair
- critical temp.

reflected in many body BCS state!

Origin of attractive interactions

Repulsion energy between $V(q) = \frac{e^2}{4\pi\epsilon_0 |q|^2}$.

(in vacuum)

But interactions also screen Coulomb $\times \eta$.

\rightarrow interaction with the ions of system.

\Rightarrow Polarization \vec{P} of environment.

\Rightarrow electrical induction $\vec{D} = \epsilon_0 (\vec{E} + \vec{P})$
 \hookrightarrow electrical displacement

Since \vec{P} & \vec{E} are collinear,

$$\vec{D} = \epsilon_0 \epsilon_r \vec{E}$$

$\vec{P} = (\epsilon_r - 1) \vec{E} \rightarrow \epsilon_r \rightarrow$ relative dielectric constant of medium $\frac{\epsilon_r}{\epsilon_0}$

\Rightarrow Screening!

$$V_q \sim \frac{1}{q^2}$$

$$V_q = \frac{1}{q^2 + \kappa_s^2} \sim \frac{1}{q^2}$$

$$V_q = \frac{e^2}{4\pi\epsilon_r(\vec{q}, \omega) \epsilon_0 |q|^2}$$

$\epsilon_r(\vec{q}, \omega) \rightarrow$ dielectric response of system when

we insert an ext. charge whose density has wave vector q & varies in time with freq. ω . [\vec{E} field varies with the wave length of field]

$$\vec{E}(\vec{q}, \omega) = \vec{E}_q e^{i(\vec{q} \cdot \vec{r} + \omega t)}$$

All the energy the ion is now displaced —

$$\vec{\xi}(\vec{q}, \omega) = \vec{\xi}_q e^{i(\vec{q} \cdot \vec{r} + \omega t)}$$

Classical mechanics dictates

$$M \frac{d^2 \vec{\xi}}{dt^2} = -\alpha_q \vec{\xi} + e \vec{E} \rightarrow \text{electric drift.}$$

↓ elastic restoring force.

M — mass of ion. (monovalent with charge +e)

In Fourier space)

$$-M\omega^2 \vec{\xi}_q = -\alpha_q \vec{\xi}_q + e \vec{E}_q$$

Polarization correspond to $\vec{\xi}_q$ is

$$\vec{P}_q^{ion} = \frac{n_{ion} e}{\epsilon_0} \vec{\xi}_q$$

n_{ion} → density of ions.

$$\vec{P}_q^{ion} = \frac{n_{ion}}{\epsilon_0} \cdot \frac{e \vec{E}_q}{\alpha_q - M\omega^2}$$

ω_p → plasma freq. of ions

$$= \frac{\omega_p^2}{\Omega^2 - \omega^2} \vec{E}_q$$

$$\omega_p^2 = \frac{n_{ion} e^2}{M \epsilon_0}$$

$\Omega = \sqrt{\frac{\alpha_q}{M}}$ → phononic frequency (elastic forces)

Electronic polarization

$$\vec{p}_q^{\text{el}} = \frac{\omega_p^2 \vec{E}_q}{\omega_p^2 \lambda_s^2 q^2 - \omega^2}$$

Thomas term
 $\lambda_s \rightarrow$ screening length
 for e^-

$$\lambda_s \sim a$$

$$\lambda_s q \sim \frac{1}{q}$$

neglecting ω^2

$$\vec{p}_q^{\text{el}} = \frac{\vec{E}_q}{\lambda_s^2 q^2}$$

(Thomas-Fermi approx)

$$\vec{p} = \vec{p}^{\text{ion}} + \vec{p}^{\text{el}}$$

$$\epsilon_r(q, \omega) - 1 = \frac{1}{q^2 \lambda_s^2} + \frac{\omega_p^2}{\Omega^2 - \omega^2}$$

$$\frac{1}{\epsilon_r(q, \omega)} = \frac{\Omega^2 - \omega^2}{\omega_p^2 + \epsilon_{\text{el}}(\Omega^2 - \omega^2)}$$

$$\epsilon_{\text{el}} = 1 + \frac{1}{q^2 \lambda_s^2}$$

$$\Omega_{\text{ph}} = \left[\Omega^2 + \frac{\omega_p^2}{\epsilon_{\text{el}}} \right]^{\frac{1}{2}}$$

$$\Omega < \omega < \Omega_{\text{ph}}$$

$$\epsilon_r \text{ is } < 0$$

Attraction is stronger if $\Omega \rightarrow 0$.

as a result $V(q, \omega)$ can be negative.
